wetransfer

WeTransfer HTML5 Wallpaper API

Please read this whole document carefully before starting work on your advert.

In addition to standard image and Flash backgrounds WeTransfer is now also offering advertisers the ability to create beautiful HTML5 backgrounds. This document is to help you produce your own content.

Ensure you have the latest version of this document and it's related files

The latest version of this document is to be found at http://we.tl/html5api
If you only have this PDF with no related files, download the full package from the above URL.

Examples and testing your own code

Included in this package are some examples and a WeTransfer test environment which you can access via index.html, which you should run via a (local) webserver. You can use this to open your adverts in an environment that emulates WeTransfer. In the source of the index.html you can enter a list of HTML pages which the environment will open in the background randomly every 45 seconds.

The test environment needs to run through a webserver to allow crossorigin messaging to work which is required for the HTML5 Wallpaper API. Running files locally through a browser will -not- work.

For debugging the API you can use the browser's built-in console.log, debug, info, warn, error methods will appear in the browser's console. The API in the test environment will also output some information about wallpaper rotation so you can confirm it is working.
We only accept good quality adverts at WeTransfer. The examples we supply are purely for showing how to use the various functions available with the minimum of code, and obviously not to suggest any sort of quality benchmark!

Browser support and Browser testing

HTML5 Wallpapers will only be shown to the the following browsers.

Browser name	Google Chrome	Mozilla Firefox	Apple Safari	Internet Explorer
Minimum version	30	30	6.1	10
Browser testing	latest-1	latest-1	6.1+	10+

Test as appropriate and try to think about graceful degradation and/or progressive enhancement for features if needed. For testing we recommend the following browsers.

Please make sure you test in different browsers and take advantage of the responsive options using media queries.

Video

We know from feedback from our users that people don't like videos that start automatically, so we require all videos to start from a still image, with user interaction required to play the video. Also please make sure your video is available in various video codecs that are supported in all the aforementioned browsers.

Audio

We do not allow audio to play in an advert before interaction. This means that no music or sound effects can play until the user has actually made an effort to interact with the advert (for instance clicking on a 'play video' or 'play game' button).
If there is a lot of sound, please create a 'mute' button - or better still, a volume control.

External assets

When using external assets please try to use as few as possible, for example by combining images into sprite maps or using data-uri's whenever possible. We will require your assets to be stored in a certain location and reference by an absolute URL via our CDN, usually similar to this:

```
https://backgrounds.wetransfer.net/<client>/<file>
```

Please contact us so we can tell you the location to place the files. You should place a variable in your code holding the location for these assets so that you can test with them in your test location, and when it goes live it can be easily changed to the location that we supply.

File Sizes

Your advert could be viewed millions of times. Before a user can see your ad, it has to be firstdownloaded. For this reason, we like to ensure that the file sizes of your wallpaper is kept at aminimum.
Our general rule is that the page should preferably be no more than 2MB. If you are using a videoin your wallpaper then we will allow it to total 5MB. Anything that loads after interaction using a preloaded can be any size under 50MB.
Please ensure that you remove any unused assets that could be taking up extra space.

Delivering your finished result to us

We require to submit all your source code for us. This is so that we can check for security issues and, if necessary, help you with debugging. Please include all external assets (images, stylesheets, javascript, fonts etc.)

Sizing

Your wallpaper will be loaded into an iframe that has the same dimensions as the viewport, using the HTML5 Wallpaper API you will be able to get the position and dimensions of the WeTransfer app and we advise using as much scalable and responsive options as possible for your advert to make sure it looks good everywhere. There are many ways to make your advert look nice in HTML (with CSS3, SVG, font-face etc.).
We recommend that you build your wallpaper with emphasis on 16:10 sized screens. Bear in mind, though, that about 25% of our users are still using 4:3 screens. Don't put any important info outside of the 4:3 area.

Using the WeTransfer Javascript API

To use API calls, your advert must be made aware of the WeTransfer environment. In order to do this you simply "need to include the API Javascript file

```
<script type="text/javascript" src="https://assets.wetransfer.net/js/wallpaper-api-1.0.js">
</script>
```

Please put this before your closing `</body>` tag and all your own Javascript underneath it. By including this file your advert will become aware of it's surroundings and expose API calls on a "`wetransfer`" object. More about this in the next chapters.

Position of the WeTransfer app

You can find out the position of the WeTransfer app. You can also move it out of the way to the edge of the screen to provide more screen estate (however, this is only allowed upon user interaction)
The `wetransfer` object has a method that returns an object with the X, Y, width and height of the WeTransfer app. This is an example:

```
wetransfer.appPosition(function(rect){
console.log(rect.x, rect.y, rect.width, rect.height);
});
```

It's that simple!

If you want to hide the WeTransfer app to the edge of the screen, simply use the following command.

```
wetransfer.appHide();
```

The app will remain in that position until the user clicks on the app or the advert changes. You can also programmatically bring the WeTransfer app back

```
wetransfer.appShow();
```

Clicking through your advert

Every advert has a click-through URL, the web address that is visited when the user clicks on the ad. This address is stored in WeTransfers' advert database and is not presented to your advert, in order to make something (or the entire advert) clickable please use the following code.

```
wetransfer.click();
```

Language

WeTransfer is available in multiple languages, you can retrieve the current language WeTransfer is set to in order to make your advert multilingual as well. The API call will return an ISO 639-1 code of the language.

```
wetransfer.language(function(lang){
console.log('interface language:', lang);
});
```

In the test environment you can also change the language by changing line 18 in index.html

The advert timer

Each advert is shown on WeTransfer only for a certain length of time (usually 45-60). However, one of the benefits of the HTML5 backgrounds is the opportunity to pause or reset the timer while the user is busy interacting with your advert. For instance, your advert might be a game, and while the user is playing you can stop the timer so that WeTransfer won't display a new advert and spoil their fun, and reset it once the game is finished so the user can see their score. Similarly, you could pause the timer while a video is playing and resume it when the video stops. If you have loaded the WeTransfer Javascript API you can call the pauseTimer, resumeTimer and resetTimer functions. As shown here:

```
wetransfer.pauseTimer();    // Do something, i.e. show a video of me dancing
wetransfer.resumeTimer();   // This will resume the timer again
wetransfer.resetTimer()     // This resets the timer "
```

The API also has a call available that returns the amount of seconds you have left, this is available in

```
wetransfer.remainingTime(function(seconds){
console.log('timer visible for:', seconds);
})
```

If you pause the timer, make sure to restart it as well if the user stops interacting. If not we can not run the wallpaper.

Tracking events with VAST

You can track how users interact with your advert. We use a system based on VAST (Video Ad Serving Template). As the name suggests it is generally used to track how users view videos, though it can be used for other events outside of the video. You should tell us that you are using VAST tracking in your wallpaper.
These are events that can be tracked:

```
start midpoint firstQuartile thirdQuartile complete mute unmute
pause rewind resume fullscreen expand collapse acceptInvitation close
```

In a typical video advert, you would capture most of these events while the video plays, and use the API call shown below to tell WeTransfer what event has occurred and, if you have more than one, on which video. These events will be stored by our advert server and presented in the end report.
To make the call you can simply use:

```
wetransfer.vast('creativeView');
```

Replace creativeView with whatever event you want to fire. The event is case sensitive.

If you are showing more than one video, you can track each one individually. Simply pass the basic filename along with t'he call. You will need to give us the list of filenames of the videos.

```
wetransfer.vast('creativeView', 'video1.mp4');
```

You can also use this to track events even if you're not using video. You can call any VAST event in place of an event in your advert. For example, if you wanted to track if a game is won, you could choose the 'fullscreen' event. Since 'fullscreen' doesn't make sense out of context, you should make sure that you let us know what VAST events belongs to which event.
